### Abstract

Regarding the Coronavirus Disease 2019 (COVID-19) in Republic of Korea (Korea), the government intends to evaluate the domestic situation and respond to variant viruses by checking current status, dynamics, and the clinical characteristics of the COVID-19 on a monthly basis.

COVID-19 virus variant surveillance was conducted through full-length genome analysis and spike protein gene analysis for positive samples of confirmed cases related to various domestic outbreaks and imported cases.

The epidemiological and clinical characteristics were analyzed using initial and in-depth epidemiological investigation results reported through the Korea Disease Control and Prevention Agency's (KDCA) COVID-19 information management system; the information system for managing confirmed patients, wired monitoring. Clinical characteristics such as severity and the occurred of group cases were analyzed.

Among the number of confirmed cases during the March (13,288), 12.0% of isolates (1,589) was laboratory tested for identification of variants of SARS-CoV-2. A total of 113 accounting for 7.1% of the tested were confirmed as Variants of Concern (VOC). The rate of sequenced isolates of March were increased by 33% compared to that of February. On the other hand, the detection rate of VOCs of March were decreased by 4.3% compared to that of February.

A total of 330 patients of Variants of Concern (VOCs) have been confirmed in Korea to April 5, 2021. The 330 VOC cases were divided into three groups: 501Y.V1, 501Y.V2 and 501Y.V3. 280 cases (84.9%) having the 501Y.V1, 42 cases (12.7%) having the 501Y.V2 (VOC originating from the South Africa), and 8 cases (2.4%) having the 501Y.V3 (VOC originating from the Brazil). Among the 330 cases, there were 204 imported cases (61.8%). The patients' average age was 38.1. By age group, people aged 71 cases (21.5%) each in their 20s, 30s. 233 cases (70.6%) were Korean nationals. 192 cases (58.2%) were symptomatic at diagnosis, 69 cases (20.9%) was mild respiratory symptoms with fever. Most symptoms of VOC patients in Korea were mild, but 9 case of the 501Y.V1 (VOC originating from the UK), and 1 of the 501Y.V2 (VOC originating from the South Africa) patients were severe/critical (including one death). The rate of severe/critical symptoms was 3.0%, and the fatality rate was 0.3%.

A total of 7 VOCs-related group cases were confirmed in March 2021, with 153 confirmed cases (32 laboratory confirmed cases, 121 epidemiological cases) lower than February 910 group cases, 195 confirmed cases [65 Laboratory confirmed cases, 130 epidemiological cases]. There were a total of 19 VOCs-related group cases and 394 confirmed cases (117 laboratory confirmed cases and 277 epidemiological related cases). By gender, there were 223 male cases (56.6%) and 78 female cases (19.8%) aged 20-29 years, and 128 (32.5%) cases were reported in Gyeonggi Province, followed by 120 cases (30.5%) reported in Ulsan Metropolitan City.

**Keywords:** Coronavirus Disease-19 (COVID-19), Variant of Concern (VOC), Variant of Interest (VOI), Whole Genome Sequencing, Clinical characteristic, Group cases

## Introduction

Starting with a massive outbreak of pneumonia of unknown etiology in Wuhan, Hubei Province, China, in December 2019, coronavirus disease 2019 (COVID-19) expanded to become a global pandemic. In Republic of Korea (hereafter, Korea), since the first confirmed case was reported on January 20, 2020, a total of 105,752 COVID-19 cases have been confirmed as of April 5, 2021. Well over a year has passed since the first outbreak of COVID-19, and the world is now facing another phase of the pandemic due to the emergence of variants. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which is the causative agent of COVID-19, is an RNA virus that continuously accrues mutations in the process of proliferation and transmission. Since most mutations occur in areas that are unfavorable to viral survival or do not affect the characteristics of the virus, they disappear quickly or do not lead to significant changes, but certain mutations contribute to increased transmissibility or cause changes in the characteristics of the virus, such as its pathogenicity. Since it was first reported on September 20, 2020 [1], the UK variant is rapidly spreading worldwide. Recently, various variants that originated in the UK and South Africa have been spreading in many countries, and these variants have been confirmed among international travelers in Korea.

Variants can be identified through genetic analyses. Recently, whole-genome sequencing has become widely used, and various genetic information related to variants is shared worldwide through the Global Initiative on Sharing All Influenza (GISAID) database (DB) on the web and the PANGO Lineages site [2,3].

In Korea, since the first person infected with the UK variant was identified in the quarantine stage in December 2020, a total of 330 people have been confirmed to be infected with the

variant as of April 5. The UK variant is reported to have high transmissibility (1.5 times that of the original SARS-CoV-2 virus) [1,4], and the South African and Brazilian variants are also expected to have high transmissibility [5,8]. Although the possibility of immune evasion depending on the site of mutation has been reported [6,7], further research is still needed.

In order to stem the spread of variants in Korea, strengthened measures are enforced: those visiting from countries where variants of concern are prevalent are required to submit a written confirmation of a negative test and remain in a facility or private residence for quarantine after testing. However, it is necessary to establish preemptive measures for patient management based on regular and multilateral analyses of the characteristics of the ever-changing variants.

Therefore, this report aims to describe the results of surveillance of variants of concern that have been confirmed in Korea, data of additional cases of transmission of the variants, and the epidemiological and clinical characteristics of patients infected with the variants. Through steady monitoring and characterization of these variants, we seek to help establish evidence-based response strategies to manage patients infected with variants and to prevent the spread of variants.

## Methods

### 1. Status of variant surveillance in Korea

#### A. Subjects of analysis

In order to monitor the outbreak of variants in Korea, the Central Quarantine Countermeasures Headquarters has been conducting genetic analyses on representative specimens of domestic cases, considering the epidemiological association

and regional distribution among large-scale and local sporadic outbreaks. For imported cases, genetic analyses are prioritized according to the agency's internal evaluation of the risk of each country based on the prevalence of variants, countries where variants have been identified, and countries with community outbreaks, which can be identified from the GISAID DB. In particular, in order to respond to the influx of variants from abroad and the spread of these variants in Korea, it has also strengthened the surveillance and analyses of variants by referring to the information on variants of concern (VOCs) and variants of interest (VOIs) provided by the World Health Organization (WHO).

## B. Variants of concern (VOCs) and variants of interest (VOIs)

On February 25, 2021, the WHO classified VOCs and VOIs to recommend public health interventions against variants. A VOC is defined as a variant with (1) a confirmed increase in transmissibility or unfavorable epidemiological changes; and (2) increased pathogenicity or changes in the severity of clinical presentation; or (3) a confirmed decrease in the effectiveness of diagnostics, vaccines, and therapeutics or classification as a VOC by the WHO in consultation with the SARS-CoV-2 Virus Evolution Working Group. The WHO coordinates laboratory research on VOCs through the research group and conducts rapid risk assessments, communication of relevant information between member states, and revisions of guidelines. A VOI is defined as a variant with (1) a mutation in an amino acid that can show or induce different traits compared to the reference isolate and (2) community transmission, multiple infection cases, a large-scale outbreak, or detection in many countries or classification as a VOI by the WHO through consultation with the research group.

## C. WHO's addition of VOIs

On March 30, 2021, the WHO added two variants originating in France and the Philippines to the list of VOIs [1,2]. The Philippine variant (B.1.1.28.3), which was first identified in the Philippines in February 2021, belongs to the B.1.1.28.3 (P.3) lineage of the GR clade, and is characterized by 7 amino acid mutations of the spike (S) protein (L141/G142/V143 deletion, E484K, N501Y, D614G, and P681H), and is currently confirmed in six countries including the Philippines, Japan, and the UK. The B.1.1.28.3 variant shares the E484K mutation, which is found in the South African and Brazilian variants, suggesting the possibility of immune evasion.

The French variant, which was first identified in France in January 2021, belongs to the B.1.616 lineage of the GH clade and is characterized by 9 amino acid mutations of the S protein (G142 deletion, D66H, Y144V, D215G, V483A, H655Y, G669S, Q949R, and N1187D), but additional confirmation and research are needed in relation to its transmissibility, virulence, and immune response.

## D. Results of genotyping and surveillance of COVID-19 variants in Korea

As of April 5, 2021, the Korea Disease Control and Prevention Agency (KDCA) conducted genetic analyses of a total of 5,774 cases (4,567 domestic cases and 1,207 imported cases; 5.6% of all confirmed cases in Korea). In particular, since December 28, 2020, when overseas variants were first confirmed among incoming international travelers in Korea, the KDCA has been continuing to expand its analytical capacity: from late February, variant analyses have also been conducted at five regional disease response centers and a genetic analysis targeting only the S protein has been added to the whole-genome analyses, which contributes to the enhanced analytical capacity

by shortening the analysis time (which takes at least 3 to 4 days). As a result, the number of analyses increased by approximately three times in March (1,589 cases are currently being analyzed as of late March) compared to January (587 cases were analyzed) (Figure 1).

As a result of the whole-genome analysis (4,319 cases) of the clades of SARS-CoV-2, various clades have been identified in imported cases, but overall, GH was the most common with

39.6%, followed by GR (31.4%), GRY (11.8%), and G (11.0%).

Among imported cases, the proportion of the GRY clade increased significantly from 8.3% in December 2020 to 34.8% in February 2021 and 22.7% in March 2021. Among domestic cases, S and V clades were confirmed in many cases until April 2020, but the GH clade has accounted for the majority (90.7%) since the Itaewon club outbreak in May, indicating that it is still the predominant strain in Korea (Figure 2). The proportion of

Figure 1. The number of sequenced Coronavirus Disease-19 (COVID-19) virus and the rate of sequenced isolates among the confirmed cases

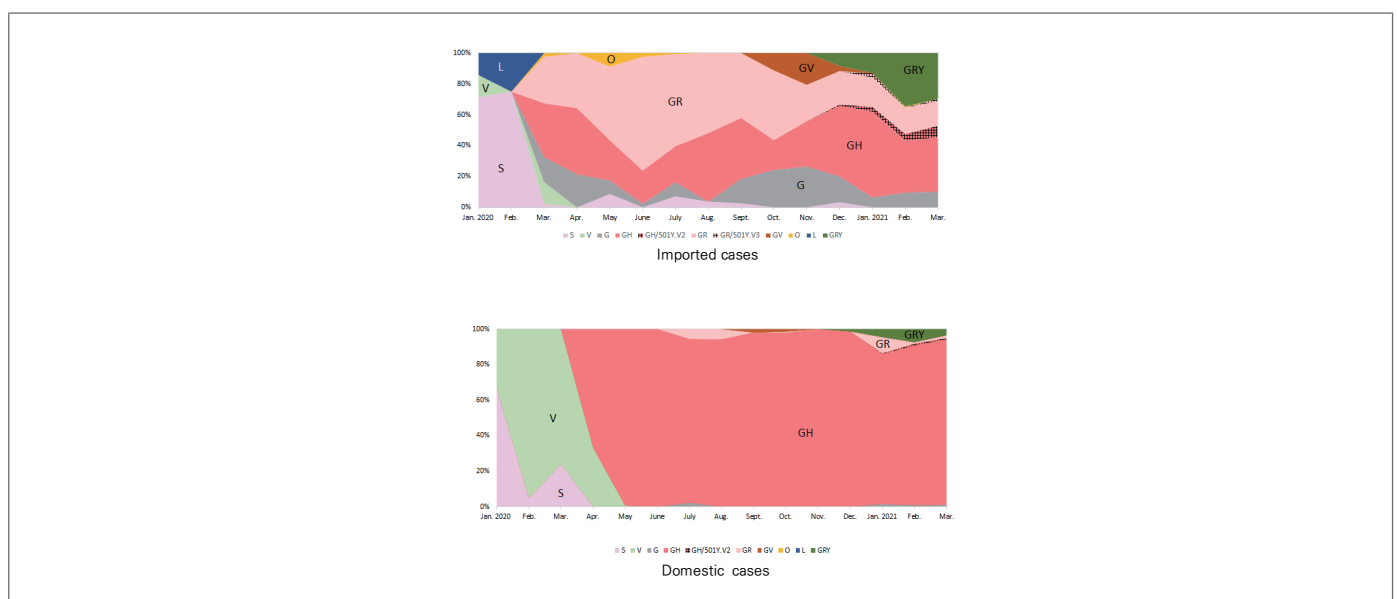

Figure 2. The distribution of the clades of Coronavirus Disease-19 (COVID-19) virus in domestic and imported cases

the GRY clade, which corresponds to the UK variant (501Y.V1), was found to be 1.3% in December 2020, 7.4% in February 2021, and 3.6% in March 2021. There was a significant difference in the clade distribution between the imported cases and domestic cases, and for overseas cases, it seems that the inflow of variants has occurred in proportion to the dominance of VOIs that are rapidly increasing in countries around the world, leading to the identification of the same variants in domestic cases.

From December 2020 to April 5, 2021, VOCs were confirmed in a total of 330 cases (8.5%) in Korea, of which the 501Y.V1 variant was found in 280 cases (7.2%), the 501Y.V2 variant in 42 cases (1.1%), and the 501Y.V3 variant in 8 cases (0.2%). Among the 1,589 specimens analyzed in March, VOCs were found in a total of 113 cases (7.1%), the 501Y.V1 variant in 93 cases (5.9%), the 501Y.V2 variant in 19 cases (1.2%), and the 501Y.V3 variant in 1 case (0.1%).

Since it was first confirmed in 14 cases (2.8%) in December 2020, the 501Y.V1 variant has been identified in 51 cases (8.7%) in January 2021, in 122 cases (10.3%) in February, and in 93 cases (5.9%) in March, indicating that it increased until February, but decreased slightly in March (Table 1, Figure 3). Of the total 280 cases with the 501Y.V1 variant, 164 cases (58.6%) were confirmed in imported cases and 116 cases (41.4%) were confirmed in domestic cases; thus, the variant was more commonly identified in imported cases. The imported cases were confirmed among international travelers from a total of 32 countries including Hungary (37 cases), the United Kingdom (19 cases), Poland (14 cases), UAE (12 cases), and Pakistan (12 cases) (Table 2). As for the domestic cases, the largest number of cases (48 cases, 10.9%) was detected in the Gyeongnam region (7 cases [9.5%] in January 2021, 19 cases [15.7%] in February, and 22 cases [11.6%] in March). As for the 501Y.V2 variant, 32 of 42 cases (76.2%) were related to the entry of international travelers from a total of 14 countries, including Tanzania (8 cases), Bangladesh (5), and UAE

(4 cases). All 8 cases with the 501Y.V3 variant were international travelers from a total of 4 countries including Brazil (5 cases), Canada (1 case), and Saudi Arabia (1 case) (Table 2).

The L452R.V1 variant, which is a VOI that originated in California, USA, has been identified in 193 cases since December 2020 (13 cases in December 2020 [2.6%], 21 cases in January 2021 [3.6%], 59 cases [5.0%] in February, and 100 cases [6.2%] in March), of which 29 cases were confirmed among international travelers from the USA (27 cases) and Mexico (2 cases), and among the 164 domestic cases with the variant, the largest number of cases (96 cases, 33.9%) was identified in the Gyeongbuk region. Of the 6 cases with the B.1.526 variant originating in New York, USA, 4 cases were confirmed among international travelers from the USA after February 2021. The 484K.V3 variant was confirmed in 7 cases among international travelers entering the country from Nigeria (4 cases) and Sudan (1 case) after February 2021, and the B.1.1.28.3 variant was confirmed in the international travelers from the Philippines (5 cases) after February 2021, indicating that the inflow of several variants has been confirmed during the surveillance process since February. The B.1.616 variant, which originated in France, has not been identified yet in Korea.

In recent months, several variants have spread rapidly around the world, raising concerns about the inflow of variants into Korea. To respond to this, it is necessary to steadily conduct surveillance and analyses of variants, as well as monitoring the occurrence of variants in each country.

Table 1. The regional occurrence of Coronavirus Disease-19 (COVID-19) variants in the Republic of Korea (Up to April 5, 2021)

Region		Number of VOC (Detection rate, %)*							
		Total	Dec. 2020	Jan. 2021	Feb. 2021	Mar. 2021

## 2. Clinical and epidemiological characteristics of patients with VOCs

### A. Analysis subjects and methods

After the first confirmed case infected with a variant in Korea in December 2020, 330 confirmed cases of VOCs were analyzed, including 168 patients 501Y.V1, 501Y.V2, and 501Y.V3 confirmed by April 5, in addition to the 162 patients with VOCs who had been included in the first round of analysis until March 1, 2021. The 330 subjects included 280 people with the 501Y.V1, 42 people with the 501Y.V2, and 8 people with the 501Y.V3. The frequency analysis and chi-square test of epidemiological investigation records and clinical data of patients with basic variants were performed using SPSS, and epidemiologic and clinical characteristics were analyzed.

## Result

### 1. Route of infection and detection

The route of infection and detection was investigated among a total of 330 people confirmed to have 501Y.V1, 501Y.V2, and 501Y.V3 from December 2020 to April 5, 2021. Regarding the route of infection, 204 patients (61.8%) were imported cases, of whom 116 patients (35.2%) were confirmed during home quarantine after entry, followed by 85 patients (25.7%) confirmed during entry screening and 3 patients (0.9%) confirmed through post-entry diagnostic tests. Among the 126 patients (38.2%) with locally acquired infections, the route of infection was contact with confirmed cases in 116 patients (35.2%) and under investigation in the remaining 10 patients (3.0%) (Table 3).

### 2. Epidemiological characteristics

\* Home quarantine exemption

501Y.V1 was the most common. Of the total 330 patients, 280 patients (84.9%) had the 501Y.V1, which was more prevalent in men (175 patients, 62.5%) than women (105 patients, 37.5%). The largest number of people was in the age group of 20 to 29 years (62 patients, 22.1%), followed by 30 to 39 years (57 patients, 20.4%) and 40 to 49 years (53 patients, 18.9%). The most frequently used isolation treatment facilities were hospitals (151 patients, 53.9%), followed by community treatment centers (126 patients, 45.0%) and others (2 patients, 0.7%). There were 9 (3.3%) critical/severe patients, including death (Table 4).

## B. 501Y.V2

The 501Y.V2 was found in 42 (12.7%) of the 330 patients

with VOCs. There were more men (27 patients, 64.3%) than women (15 patients, 35.7%), and the most common age group was 30 to 39 years (11 patients, 26.1%), followed by 20 to 29 years and 40 to 49 years, with 7 patients (16.7%) each. The most commonly used isolation treatment facilities were residential treatment centers (26 patients, 61.9%), followed by hospitals (16 patients, 38.1%). There was one (2.4%) with critical/severe patient (Table 4).

## C. 501Y.V3

Of the total of 330 patients confirmed to have VOCs in Korea, 8 (2.4%) had the 501Y.V3. There were more men (6 patients, 75.0%) than women (2 patients, 25.0%), and the number

\* Death before COVID-19 confirmation, Unmanaged case; \*\*  $\chi^2$  test

of patients aged 30 to 39 years was 3 (37.5%), those aged 20 to 29 years and 60 to 69 years were 2 (25.0%) each, and 1 patient (12.5%) was in the age range of 50 to 59 years. Residential treatment centers were the most common isolation treatment facilities, with 5 patients (62.5%), and hospitals were used in 3 patients (37.5%). There were no critical/severe patients including death (Table 4).

### 3. Clinical characteristics

Among the patients with VOCs in Korea, 192 patients (58.2%) reported symptoms and 138 patients (41.8%) were asymptomatic. Excluding asymptomatic cases, the most common symptom among the symptomatic cases was mild respiratory symptoms (cough, etc.) unaccompanied by fever in 69 patients

(20.9%). There were 43 patients (13.0%) who complained of mild respiratory symptoms with fever, 28 patients (8.5%) had fever only, 24 patients (7.3%) had other symptoms only, 23 patients (7.0%) had other symptoms (chills, abdominal pain, etc.) accompanied by fever, and 5 patients (1.5%) lost their sense of smell or taste.

In Korea, patients who undergo isolation with high-flow oxygen therapy, a ventilator, extracorporeal membrane oxygenation (ECMO), and continuous renal replacement therapy (CRRT) are classified as critical/severe. The main complaints of the patients with VOCs in Korea were mostly mild, but 9 (including 1 death) of those with the 501Y.V1 and 1 of those with the 501Y.V2 were critical/severe. The proportion of critical/severe (including death) among the patients with VOCs in Korea was 3.0% and the fatality rate was 0.3% (Table 5).

#### 4. Current status of large-scale outbreaks related to VOCs

In March 2021, there were 7 confirmed large-scale outbreaks of VOCs and 153 confirmed cases related to VOCs (32 laboratory-confirmed cases and 121 epidemiologically related cases), exceeding the corresponding numbers confirmed in January (2 large-scale outbreaks; 46 confirmed cases [20 laboratory-confirmed cases and 26 epidemiologically related cases]), but reflecting lower numbers than those reported in February (10 large-scale outbreaks; 195 confirmed cases [65 laboratory-confirmed cases and 130 epidemiologically related

cases]).

There were a total of 19 large-scale outbreaks of VOCs and 394 confirmed cases (117 laboratory-confirmed cases and 277 epidemiologically related cases), and the variant responsible for the 19 large-scale outbreaks was 501Y.V1 in 17 cases (89.5%) and 501Y.V2 in 2 cases (10.5%) (Table 6).

Regarding the demographic characteristics of the 394 cumulative confirmed cases in large-scale outbreaks of VOCs, there were more men (233 people, 56.6%) than women (171 people, 43.4%). The largest number of people was in the age range of 20 to 29 years (78 people, 19.8%), followed by 50 to 59 years (75 people, 19.0%), 30 to 39 years (65 people, 16.5%), 40 to 49 years, and 0 to 9 years (48 people, 12.2%). By region, Gyeonggi-

## Conclusion

The Central Quarantine Countermeasures Headquarters has continued to analyze the genetic characteristics of COVID-19 through whole-genome genetic analyses and has expanded its analytical capacity, leading to the identification of the VOCs (501Y.V1, 501Y.V2, and 501Y.V3) and VOIs (452R.V1, B.1.526, 484K.V3, and B.1.1.28.3). In recent months, several variants have been spreading rapidly abroad, thereby raising concerns about the inflow of these variants into Korea. To respond to this situation, it is necessary to perform ongoing surveillance and analyses of the variants, as well as monitoring the occurrence of variants by country.

Although VOCs have been reported to have increased transmissibility and fatality rate, no significant difference was noted in the severity rate and fatality rate between the patients with the existing virus and those with the VOCs in Korea. Nonetheless, studies on these variants are in progress, and infections with the variants continue to occur in Korea; thus, ongoing monitoring and analyses of the clinical characteristics of the patients infected with variants are necessary.

The 501Y.V1 variant was confirmed to be responsible for most of the large-scale outbreaks of VOCs in Korea. VOCs, including the 501Y.V1 variant, have been found in many countries around the world, and increased transmissibility and risk of death and the possibility of immune evasion have been reported [1]. In order to suppress the COVID-19 outbreak, Korea has been making efforts to prevent further spread through vaccinations and epidemiological investigations. In order to strengthen the management of variants, related information has been shared with local governments, testing has been expanded to the contacts of confirmed patients, and the surveillance of variants has been strengthened in local communities including areas with large concentrations of foreigners.

**Submitted:** April 23, 2021; **Revised:** April 26, 2021;

**Accepted:** April 27, 2021

**① What was known?**

Since 162 people were confirmed to be infected with VOCs in Republic of Korea (Korea) as of March 31, 2021, 168 people have been additionally identified to have VOCs, which brings the total number of people with VOCs to 330, including 280 people with the UK variant, 42 people with the South African variant, and 8 people with the Brazilian variant.

**② What does this study add?**

Since it was first identified in 15 cases (3.0%) in December 2020, the 501Y.V1 variant has been confirmed in 51 cases (8.7%) in January 2021, 127 cases (10.7%) in February, and 87 cases (5.2%) in March. The L452R.V1 variant was also confirmed in 14 cases (2.8%) in December 2020, 21 cases (3.6%) in January 2021, 60 cases (5.1%) in February, and 98 cases (6.2%) in March. In addition, the B.1.1.28.3 variant, which was first identified in the Philippines, has been confirmed in 5 travelers from the Philippines since February 2021. Among the 330 people with variants, there were more men (208, 63.0%) than women (122, 37.0%). By age group, 20 to 29 years and 30 to 39 years were the most common with 71 people (21.5%) each and the average age was 38.1 years. Among the patients with VOCs in Korea, 192 (58.2%) were symptomatic and 138 (41.8%) were asymptomatic, and the largest number of people (69 cases, 20.9%) complained of only mild respiratory symptoms without fever. Nine severe cases (including 1 death) occurred among those with the 501Y.V1, as well as 1 critical/severe of the 501Y.V2.

**③ What are the implications?**

In order to stem the inflow and spread of variants in Korea, it is necessary to provide rapid response measures by strengthening the surveillance of variants and to establish a scientific basis through the analysis of the characteristics of variants. In particular, an evidence-based response strategy for the management of patients with variants should be established by comparing and analyzing the severity and fatality rates based on regularly monitoring the clinical conditions of patients with variants.

### Abstract

After being confirmed as 501Y.V1 on September 20, 2020, about 125 countries have confirmed the 501Y.V1, and the recent COVID-19 pandemic in Brazil has become serious due to the 501Y.V3[1]. A total of 330 Variant of Concern (VOCs) were confirmed by April 5, after the first case was confirmed in Republic of Korea in December 2020. Since January 2, 2021, the Central Disease Control Headquarters has been managing VOCs and suspects by applying "the enhanced case management guidelines" to prevent the inflow and spread of variant in Korea. Therefore, we decided to derive an appropriate isolation period based on scientific grounds for analysis, which accounts for guidance on discharging patients with 501Y.V1 in Korea.

Except for factors such as severe/critical, death, etc. that may affect the transmission period; 501Y.V1 group was selected for 78 and Non-501Y.V1 group for 311 (May, 2020). Further analysis was conducted on 522 501Y.V1 and 522 Non-501Y.V1 group (May, 2020) including 211 unconfirmed  $C_t$  values in Polymerase Chain Reaction (PCR) tests during isolation, 851 Non-501Y.V1 group (April, 2020) to comprised the difference between the period of PCR negative conversion. The distribution of  $C_t$  values in PCR tests was similar during isolation between the 501Y.V1 group and the Non-501Y.V1 group (May, 2020), and within five days of symptoms or confirmed date, 10 samples with  $C_t$  value (RdRp) below 24.68 were negative, and the remaining 30 samples were negative.

In addition, the median was 30 days for 501Y.V1 group, 33 days for non-501Y.V1 group (April, 2020) and 26 days for non-501Y.V1 group (May, 2020) with differences in the distribution of infection routes. The difference in period of PCR negative conversion is expected to take into account the impact of patient characteristics (such as underlying disease and age) according to infection routes rather than infection with COVID-19 variant.

The analysis is meaningful in that it has been able to lay the groundwork for clinical-based guidance on discharging patients as a way to manage patients with the 501Y.V1 by confirming that transmission period of the 501Y.V1 is no different from the COVID-19. In the future, it is necessary to establish a scientific evidence-based strategy to respond to VOCs by continuously analyzing the epidemiological and clinical information of patients with 501Y.V2., 501Y.V3. as well as from the 501Y.V1.

**Keywords:** Covid-19, Variant of Concern (VOC), 501Y.V1, Transmission period

## Introduction

It has been a year since coronavirus disease 2019 (COVID-19) pandemic began, and the world is facing another rise in cases due to variants of COVID-19. After the 501Y.V1 (originating from the United Kingdom) was confirmed on September 20, 2020, 501Y.V1 has been confirmed in approximately 125 countries, and the recent addition of 501Y.V3 (originating from Brazil) has further exacerbated the situation [1]. Since the first detection of 501Y.V1 in Republic of Korea (hereafter, Korea) during quarantine in December 2020, as of April 27, 2021, 535 cases of variants of concern (VOCs) have been confirmed.

To prevent the inflow and spread of variants in Korea, since January 2, 2021, the Central Disease Control Headquarters (CDCH) has been managing VOCs and suspected cases using the Enhanced Case Management Guidelines. According to the strengthened management plan, confirmed patients from abroad are isolated and controlled in a single room, and additional test-based guidance is required for confirmed or suspected cases of VOCs, as these patients are only discharged after two consecutive negative polymerase chain reaction (PCR) tests.

However, the mandatory enforcement of the test-based guidance on discharging patients has inevitably lengthened the isolation period for confirmed and suspected cases of VOCs. This has led to increased financial instability and psychological suffering for patients and less efficiency in the use of medical resources.

Hence, by analyzing the length of the transmission period of 501Y.V1, which is the most common VOC in Korea, the aim of this study was to derive an appropriate end isolation period and establish scientific evidence-based guidance for discharging patients.

## Methods

This research aimed to verify the differences in the length of transmission period between 501Y.V1 and non-501Y.V1 by comparing the timing of PCR-negative conversion along with the  $C_t$  value distribution of the PCR tests and culture tests during isolation. A cohort study was conducted from December 28, 2020 to March 15, 2021 on 178 patients who have been confirmed with 501Y.V1. R was used to conduct frequency analysis and cross-analysis (using the chi-square test) to compare epidemiological characteristics. A Kaplan Meier survival curve was constructed and the log-rank test was used to analyze the length of transmission period, and the  $C_t$  value distribution of the specimens during isolation was analyzed using a scatter plot.

### 1. Subjects of analysis

#### A. 501Y.V1 Group

Between December 28, 2020 and March 15, 2021, there were a total of 178 confirmed cases of 501Y.V1 in Korea. The  $C_t$  value of the PCR test during isolation could be confirmed for all patients. To exclude factors that could affect the length of transmission period, the following subjects were excluded from the study: 7 patients who were in severe/critical condition or died; 30 patients who did not complete the isolation treatment; and 63 patients who were discharged according to the clinical-based guidance for discharging patients. Hence, 501Y.V1 group consisted of a total of 78 patients, who were then further divided into symptomatic (54 patients) and asymptomatic (24 patients) groups prior to analysis.

#### B. Non-501Y.V1 Group

Two separate groups were formed for the non-501Y.V1

group according to the aim of the analysis. First, to compare the timing of PCR-negative conversion, the  $C_t$  value distribution of the PCR tests, and culture tests between the 501Y.V1 group and non-501Y.V1 group, the research subjects for the non-501Y.V1 group were chosen among patients confirmed to have COVID-19 prior to September 20, 2020—and specifically, those who were confirmed in May 2020 when the GH type virus, which is currently predominant in Korea, was detected. In total, there were 728 confirmed cases of COVID-19 in Korea between May 1, 2020 and May 31, 2020 (based on the date of confirmation). Among those confirmed cases, the following subjects were excluded: 211 patients who had missing values because the  $C_t$  values of the PCR tests were unconfirmed during isolation; 10 patients who were in severe/critical condition or died; and 196 patients who were discharged according to the clinical progress-based guidance on discharging patients. There were a total of 311 patients in the non-501Y.V1 group, which were further divided into symptomatic (201 patients) and asymptomatic (110 patients) groups to analyze the  $C_t$  distribution pattern of PCR tests and PCR-negative conversion during isolation.

Second, to compare differences in the timing of PCR-

negative conversion according to the infection route, patients infected outbreaks at hospitals/nursing homes in April 2020, and those infected in May 2020, when regional group outbreaks were common, were considered as the non-501Y.V1 groups for comparisons. There were 886 patients who were confirmed with COVID-19 in Korea between April 1, 2020 and April 30, 2020 (based on the confirmation date). To eliminate factors that may affect transmission period, the following subjects were excluded: 27 patients who were in severe/critical condition or died, and 8 patients who were discharged according to the clinical progress-based guidance on discharging patients. Hence, the first non-501Y.V1 group (May 2020) was composed of 522 patients (including 211 patients whose  $C_t$  values of PCR tests during isolation were unconfirmed) and the second non-501Y.V1 group (April 2020) was composed of 851 patients. The timing of PCR-negative conversion was analyzed in both groups.

# Results

## 1. Distribution of $C_t$ values

When comparing the  $C_t$  value distributions in the PCR tests during isolation between symptomatic and asymptomatic patients, no significant difference was found in the distribution of the 1,176  $C_t$  values from the 255 symptomatic patients and the 559  $C_t$  values from the 134 asymptomatic patients.

## 2. Comparison of the timing of PCR-negative conversion

The timing of PCR-negative conversion of patients infected with 501Y.V1 or non-501Y.V1 was compared between symptomatic and asymptomatic groups. In symptomatic patients, 501Y.V1 had a longer interval until PCR-negative conversion, with 31.5 days compared to the 29 days for non-501Y.V1 patients ( $p=0.026$ ). However, there were no significant differences between the two groups in asymptomatic patients ( $p=0.33$ ), with 501Y.V1 patients requiring 23 days and non-501Y.V1 patients requiring 21 days.

Furthermore, in order to evaluate the effect of the selection method for the non-501Y.V1 group, confirmed cases in April 2020 were also included in the analysis of the timing of PCR-negative

Figure 2. The distribution of  $C_t$  values between the 501Y.V1 and the Non-501Y.V1 (May, 2020)

Figure 3. The distribution of  $C_t$  values between the 501Y.V1 and the Non-501Y.V1 (May, 2020)

conversion. The median interval until PCR-negative conversion was 30 days for the 501Y.V1 group, 33 days for the non-501Y.V1 group (April 2020), and 26 days for the other non-501Y.V1 group (May 2020). Because the infections in the April 2020 non-501Y.V1 group largely occurred in group outbreaks at hospital or nursing homes in old age groups and many of the patients, the age group of the patients was high and many of the patients were in the high-risk group with underlying diseases, explaining the long interval until PCR negative conversion. In contrast, the infections in the May 2020 non-501Y.V1 group largely occurred in regional group outbreaks; therefore, this group comprised relatively young patients, fewer of whom were at risk, and had the shortest interval

until PCR-negative conversion. The differences in the timing of PCR-negative conversion appear to be more heavily affected by patient characteristics (such as underlying disease and age) and infection route, rather than the variant type.

### A. Culture test results

Culture tests were conducted on 77 positive PCR samples from 33 patients infected with 501Y.V1. Of the tested samples, 31 cases within 9 days of confirmation or onset of symptoms that had  $C_t$  values lower than 26.73 demonstrated positive culture tests, while the remaining 46 samples were all negative.

Figure 5. Survival curve between the asymptomatic 501Y.V1 and the Non-501Y.V1 (May, 2020)

Figure 6. Survival curve between the 501Y.V1 and the Non-501Y.V1 (Apr, May)

Figure 7. The distribution of  $C_t$  values and culture result between the 501Y.V1 (including clinical-based Guidance on discharging patients, Severe/critical)

\* Positive 31 patients and negative 46 patients

## Conclusion

After cases of pneumonia with an unknown cause were first announced in Wuhan, Hubei Province, China on December 31, 2019, the global COVID-19 pandemic has been continuing for over a year. Despite tremendous efforts, the pandemic still continues due to the emergence of variant viruses. 501Y.V1, for example, has demonstrated increased transmission rates (1.5 times) and fatality [1,2] and has caused another surge of cases in many nations. Hence, many nations around the world have taken

drastic measures to prevent a resurgence of COVID-19 such as closing borders. In South Korea, enhanced case management guidelines have been applied to prevent all variants of the virus from entering the country.

As a preemptive measure, mandatory test-based guidance on discharging patients has been applied for patients with variants to manage the virus conservatively. However, this analysis confirmed that transmission period of 501Y.V1 has only a negligible difference compared to that of the existing SARS-CoV-2 virus, and therefore provides a meaningful basis for

clinical-based discharge guidelines regarding 501Y.V1 patients. There still is a need for continued research regarding VOCs. Hence, epidemiological and clinical information regarding patients infected with other variants, such as 501Y.V2, 501Y.V3, must be analyzed to establish patient management strategies for cases of COVID-19 variants in Korea.

**Submitted:** April 23, 2021; **Revised:** April 26, 2021;

**Accepted:** April 27, 2021

### ① What was known?

After the first confirmed case in Korea in December 2020, 178 cases of 501Y.V1 have been confirmed as of March 15, 2021. Since January 2, 2021, the Central Disease Control Headquarters(CDCH) has applied the Enhanced Case Management Guidelines to confirmed and suspected cases of VOCs to prevent the inflow and further spread of variants in Korea.

### ② What does this study add?

The 501Y.V1 group and the non-501Y.V1 group (May 2020) both had similar distributions of  $C_t$  values from PCR tests. Culture tests showed positive results for 31 samples that were taken within 9 days of symptom onset in patients with a  $C_t$  value below 26.73, but they showed negative results for the remaining 46 samples. In addition, the 501Y.V1 group and the two non-501Y.V1 groups, which had different infection routes (April 2020, May 2020), had intervals of negative PCR conversion of 30 days, 33 days (April 2020), and 26 days (May 2020), respectively. Hence, it seems necessary to prioritize patient characteristics (such as underlying disease and age) resulting from the infection route over variant type when considering the timing of negative PCR conversion.

### ③ What are the implications?

By confirming that there were no significant differences in transmission period between the 501Y.V1 variant and the existing SARS-CoV-2 virus, this study provides the basis for the establishment of clinical-based discharge guidelines as a method of patient care. In the future, analysis of epidemiological and clinical information of patients infected with other variants, such as 501Y.V2, 501Y.V3, should be continued to establish scientific evidence-based patient management strategies for variant cases domestically.

## 초 록

흡연은 폐암, 식도암, 구강암 등 암, 심혈관질환, 호흡기질환, 백내장, 감염성 질환 등의 주요 원인이다. 이에 따라, 우리나라 성인 흡연자의 흡연행태를 파악하고 금연과 재흡연에 영향을 주는 결정요인 규명을 위해 국민건강영양조사를 활용하여 성인 총 1,018명에 대한 '성인 흡연자 패널조사'를 2015년부터 2020년까지 실시하였다. 또한, 최근 3개년도(4~6차) 추적조사 결과와 코로나19 팬데믹 상황에서 2개년도(5~6차) 추적조사 동안 참여자 흡연량 변화, 흡연 충동, 금연 광고 노출 빈도 등 요인별 특성을 심층분석 하였다. 본 심층분석을 통해 금연시도를 향상시키기 위한 흡연자의 스트레스 해소방안 마련 및 금연시도 없는 흡연자에 대한 금연지원 방안 마련의 필요성을 제시하였다. 특히, 코로나19상황 에서는 '금연을 전혀 시도하지 않음'의 비율이 39.4%에서 44.3%로 증가하였다. 향후, 흡연자 패널의 생체시료 기반 개인별 흡연 요인 분석을 통한 맞춤형 의학연구 적용 및 여성흡연자 패널을 충분히 확보한 추가연구 필요성을 제시하였다.

**주요 검색어 :** 흡연, 흡연자 패널, 흡연행태, 흡연설문, 코로나19

## 들어가는 말

성인 남성 중 흡연에 의한 사망자 수는 2012년 기준 4만 9천 명으로 전체의 34.7%를 차지한다[1]. 흡연은 폐암, 식도암, 구강암 등 성인 남성 암의 41.1%, 심혈관질환의 33.4%의 주원인으로 조사되었으며, 호흡기질환, 백내장, 감염성 질환 등 건강 전반에 악영향을 미친다[2]. 흡연 피해를 예방하고자 세계보건기구(World health organization, WHO)에서는 담배 소비 및 담배연기 노출을 줄이기 위한 담배규제기본협약(Framework Convention on Tobacco Control, FCTC)을 구성하였으며, FCTC 20조에서는 담배 소비의 규모와 패턴 파악의 필요성과 흡연 및 금연 결정요인 규명의 중요성을 강조하였다.

질병관리청은 우리나라 성인 흡연자의 흡연행태를 파악하고 금연과 재흡연에 영향을 주는 결정요인 규명을 위해 2015년부터

2020년까지 국민건강영양조사 기반의 성인 흡연자 패널을 구축하고 추적조사를 실시하였다. 본 원고에서는 지난 6년간 흡연자 패널 운영 결과 및 최근 3개년도(4~6차)와 최근 코로나19 영향의 2개년도(5~6차) 추적조사 참여자의 흡연행태 변화 및 심층분석 결과를 소개하고자 한다.

## 몸 말

### 1. 성인 흡연자 패널 운영 결과

#### 가. 패널 구축 및 흡연 설문 개발

성인 흡연자 패널은 2015년부터 2019년까지 국민건강영양조사에 참여한 대상자 중 2020년까지 연중 1회 추적조사에

동의한 현재흡연자<sup>1)</sup>와 과거흡연자<sup>2)</sup>로 구축하였다. 2015년 164명으로 시작한 패널은 2019년까지 매해 신규 패널이 추가되어 2020년 1,018명으로 최종 구축되었고 남자 989명(97.2%), 여자 29명(2.8%)으로 구성되었으며, 여자는 참여 대상자 수가 적어 분석에서 제외되었다.

추적조사의 설문은 국내 건강 관련 조사<sup>3)</sup>의 흡연 설문 문항 분석을 통해 흡연 행태변화에 영향을 주는 결정요인들을 포괄적으로 파악 후 전문가 자문회의를 거쳐 최종 문항을 확정하였다. 설문문항은 흡연행태와 결정요인으로 구분하였고, 결정요인은 개인 및 정책, 담배회사 영역으로 구분하여 구성하였다. 이후 추적조사마다 쉐련형 전자담배, 담뱃갑 경고그림 도입, 코로나19 등 흡연 이슈를 반영한 신규문항을 추가하였다. 또한, 설문문항들은 향후 각종 흡연 조사 시 활용될 수 있도록 문항은행으로 구축하였다.

## 나. 패널 유지 및 관리

패널조사에서는 탈락을 최소화하여 추적률을 향상시키는 것이 매우 중요하다. 이에, 패널 유지·관리를 위해 2018년 4차 추적조사부터 SNS(카카오톡 플러스친구)를 활용하여 패널에게 금연정보를 주기적으로 제공하고 상담서비스를 실시하는 등 상호

소통적 관리를 진행하였다. 2019년 5차 추적조사부터는 실시간으로 패널 참여를 확인할 수 있도록 어플리케이션(명칭: 스모비)을 추가 도입하였다. 어플리케이션을 활용한 실시간 설문조사를 통해 패널 관리를 하였으며, 평균 56.1%, 최대 71.4%의 설문조사 응답률을 보였다.

## 다. 추적조사 수행

추적조사는 2015년 1차 추적조사를 시작으로 2020년까지 총 6회 실시되었으며, 2018년 3차 추적조사까지 전화 설문, 4차 추적조사부터는 모바일(웹 포함) 기반의 조사 방법을 추가 병행하여 설문조사를 실시하였다. 2015년 1차 추적조사에서는 164명의 패널 중 94명이 참여하여 57.3%의 추적률을 보였다. 전화와 모바일의 병행조사로 실시한 4차 추적조사에서는 3차 참여율인 39.2%보다 9.5% 증가한 48.7%의 참여율을 보였다. 이는 모바일 기반의 패널 관리, 모바일 조사 방법으로 인한 젊은 연령층의 참여 증가에 기인한 것으로 추측된다, 신규 유입 패널 없이 진행한 마지막 6차 추적조사에서는 패널 1,018명 중 427명이 참여하여 41.9%의 추적률을 나타냈다(표 1).

1) 2015~2019년 국민건강영양조사 참여자 중 현재 담배를 피우고 있다고 응답한 사람

2) 2015~2019년 국민건강영양조사 참여자 중 최근 1년 이내 금연을 하고 있다고 응답한 사람

3) 국민건강영양조사, 지역사회건강조사, 청소년건강행태조사, 근로환경조사

## 2. 성인 흡연자 패널 추적조사 분석 결과

### 가. 추적조사 결과

2015년 1차 조사부터 2020년 6차 조사까지의 주요 결과를 살펴보면, 1차 조사에서 흡연자는 77.4%였으며, 2차 조사에서는 흡연자 분포가 81.2%로 가장 많았고, 이후 흡연자 비율이 감소하다 2020년 6차 조사에서 78.7%로 증가하는 추이를 보였다(그림 1). 금연을 시도하지 않는 이유에 대해 조사한 결과 '스트레스를 풀 방법이 마땅치 않아서'의 응답이 매해 가장 높았고 증가하는 추이를 보였다(그림 2).

흡연자 중 궤련형 전자담배를 사용하는 사람은 2017년 13.4%에서 2021년 20.1%로 6.7% 증가하였으며, 액상형 전자담배를 사용하는 사람은 2017년 17.2%에서 2020년 9.4%로 7.7% 감소하는 추이를 보였다(그림 3). 전자담배 사용 이유는 '금연하는데 도움이 될 것 같아서'의 응답이 2016년 48.6%였는데 반해 2020년 5.5%로 큰 폭으로 감소하였으며, 담배냄새가 나지 않아서 전자담배를 사용한다는 비율은 증가 추이를 보였다(그림 4).

담배 진열 노출과 그로 인한 흡연 욕구에 대해 조사한 결과 흡연자에서 평균 90%가 담배 진열을 목격한 경험이 있다고 응답하였으며, 목격한 사람 중 25%가 담배가 진열된 것을 보고 흡연 욕구가 생겼다고 응답하였다(그림 7).

### 나. 3개년도(4~6차) 추적조사 참여자의 흡연행태 변화

3개년도(4~6차) 추적조사 참여자는 203명으로 40대가 62명(31.6%)으로 가장 많았다. 흡연행태를 살펴보면, 참여자 중 155명(76.4%)은 현재 흡연을 하고 있었으며, 금연 중인 사람은 48명(23.6%)이었다. 금연 시도 유형에서는 금연을 시도하지 않은 사람이 92명(45.3%)으로 가장 많았다. 현재 흡연자 중 일반담배만 사용하는 사람이 105명(52.9%)으로 가장 많았으며, 궤련형 전자담배를 사용하는 사람이 23명(11.6%)으로 그 다음 순이었다(표 2).

4~6차 추적조사 참여자의 흡연행태 변화에 따른 영향 요인을 분석하기 위해 흡연행태 변화를 4가지로 구분하여 요인별 특성 비교를 수행하였다(표 2, 3). 금연 시도 및 유지 행태변화에 따른 요인별 특성을 '흡연 유지 변화 없음'군과 비교한 결과, '흡연시도'군에서 향후 6개월간 금연 자신감이 있는 경우 유의하게 높은 비율을 보였다. '금연 시도'군에서는 사용담배가 일반담배인

경우 유의하게 높았으며, 65세 이상인 경우와 사용담배가 궤련형 전자담배인 경우는 유의하게 낮게 나타났다. 또한 '금연 유지 변화 없음'군에서 유의하게 높은 비율을 보인 요인은 금연광고 노출 빈도가 한 달에 한 번 이상 또는 한 달에 한 번 미만으로 적은 경우, 향후 6개월간 금연 자신감이 있는 경우였으며 반대로 유의하게 낮은 비율을 보인 요인은 코로나19로 인한 흡연량 변화, 흡연 충동이 있는 경우였다(표 2, 3).

요인별 특성 비교에서 유의한 차이를 보였던 연령, 사용담배, 코로나19로 인한 흡연량 변화, 흡연 충동, 금연 광고 노출 빈도 등의 요인으로 금연 시도 및 유지 형태 변화 별 다범주 로지스틱 회귀분석을 수행하였다(표 4). 분석 결과 유의하게 나타난 요인은 없었으나, 금연을 한 번이라도 시도한 경우는 40~64세 연령층이 많았고, 동년배와 비교 시 건강 수준이 좋다고 평가한 경우는 많지 않은 것으로 나타났다.

## 다. 2개년도(5~6차) 추적조사 참여자의 코로나19로 인한 흡연행태 변화

코로나19로 인한 팬데믹 환경이 흡연행태에 어떠한 영향을 미치는지 파악하기 위하여 6차 추적조사에 관련 문항을 추가하였다. 결과 분석 시 회상편견(recall bias)이 있을 수 있는 점과 단면분석의 제한점을 고려하여 5, 6차 추적조사에 모두 참여한 패널 대상으로 코로나19로 인한 흡연행태 변화를 비교하였다.

5차와 6차 추적조사에 참여한 246명의 특성을 살펴보면 40대가 83명(33.7%)으로 가장 많았으며, 185명(75.2%)이

흡연자였다. 금연 시도 유형별 분포로는 ‘금연 시도 없음’군이 109명(44.3%)으로 가장 많았고, 흡연자의 125명(51.9%)이 일반담배만 사용하는 것으로 나타났다(표 5).

흡연행태 변화 비교를 위해 현재 흡연 상태, 금연 시도 유형, 흡연량 등을 비교하였으며, 흡연행태에 영향을 줄 수 있는 스트레스, 우울척도(Posttraumatic Embitterment Disorder Self-Rating Scale, PTEDS) 등의 요인을 분석하였다(표 6, 7). 분석 결과 현재 흡연 상태와 금연 행동단계 유형별 분포는 큰 차이가 없었다. 그러나 흡연자 중 금연을 전혀 시도하지 않은 군의 비율이 5차 35.4%에서

나쁘다	42 (17.1)	30 (16.3)	0.8	-6.3	7.9

표 7. 5차(2019년), 6차(2020년) 추적조사 연속 응답자 흡연행태 비교(2)

구분	5차 추적조사 평균(표준편차)	6차 추적조사 평균(표준편차)	t	p-value
하루 평균 일반담배 흡연량(개비)	13.6 (6.8)	13.7 (6.1)	-0.20	0.842
사용 액상형 전자담배 한 병의 평균 사용일 수(일)	11.9 (10.2)	3.4 (2.4)	3.27	0.005
하루 평균 궤련형 전자담배 흡연량(개비)	12.2 (10.2)	14.9 (6.3)	-1.19	0.238

## 맺는 말

본 연구에서는 2015년부터 2020년까지 구축된 패널 1,018명을 대상으로 총 6번의 추적조사를 수행하여 금연정책 및 환경요인에 의한 흡연행태 변화를 주기적으로 모니터링 하였다. 최근 3개년도(4~6차) 참여자를 대상으로 분석한 결과에서는 흡연자에서 '금연 시도 없음 군'이 증가하는 것을 볼 수 있었다. 코로나19 팬데믹 환경에 의한 흡연행태 변화를 알 수 있는 2개년도(5~6차) 조사에서 흡연자 중 금연을 전혀 시도하지 않은 군의 비율이 5차 35.4%에서 6차 44.3%로 증가하였으며, 여러 번 금연 시도 후 실패한 군의 비율이 5차 39.4%에서 6차 30.9%로 감소하였다.

흡연자의 금연 시도를 위해 스트레스 해소방안과 이에 대응할 수 있는 능력 향상을 위한 정부의 개입이 필요하며, 금연 시도가 없는 흡연자에 대한 금연지원 방안을 마련해야 할 것이다. 담뱃갑 경고 그림 및 문구 등의 금연정책 효과평가를 시행하고, 담배 진열 및 광고에 대한 담배규제 정책 마련이 필요할 것이다. 또한 전자담배가 금연 효과가 없음을 보여주고 있어 전자담배 사용에 대한 금연정책이 보완되어야 할 것이다.

향후 성인 흡연자 패널의 생체시료를 이용한 니코틴 수용체 분포 등 유전체 연구와 금연 약물 처방에 감수성 높은 흡연자를 구분할 수 있는 개인 맞춤형 의학 연구 방법을 적용한다면 금연과 재흡연에 영향을 주는 결정요인 규명을 명확히 할 수 있을 것이다. 또한 점차 증가하는 여성 흡연자 대상 국가금연정책 마련을 위해 여성 패널 수 증가 및 여성 흡연 원인 파악과 금연 유지를 위한 지원 마련이 필요하다.

### ① 이전에 알려진 내용은?

많은 흡연행태 관련 연구에서 스트레스 상황은 흡연행태와 관련성이 적은 것으로 알려져 있으나, 코로나19 팬데믹 상황을 반영한 본 연구에서는 흡연자가 금연을 시도하지 않고, 금연자가 금연을 실패하게 되는 가장 큰 이유로 스트레스 영향이 크게 작용하는 것을 볼 수 있었다.

### ② 새로이 알게 된 내용은?

본 연구를 통해 금연시도 유형 변화 양상은 '금연시도 없음'군과 '금연시도 후 금연 실패'군에서의 변화가 크고 반복되는 양상을 가지고 있으며, '한 번에 금연 성공'군이 금연에 실패하는 경우가 많았다. 금연시도는 하지만 금연에는 실패하는 군의 분포가 가장 많았고, 코로나19 팬데믹 상황에서 금연을 시도하지 않는 흡연자의 비율이 늘었음을 알 수 있었다.

### ③ 시사점은?

패널조사의 경우 지속적으로 신뢰도와 정확도가 확보된 응답을 얻어내기 위해 상당한 자원과 인프라가 소요되는 어려운 조사 방법임을 감안할 때 본 연구가 가지는 의미는 크다고 볼 수 있다. 이에 본 연구는 패널 유지율을 높이기 위해 SNS와 어플리케이션을 활용한 방법들을 시범 적용해 보았으며, 이를 통해 패널의 대표성을 확보하기 위해 탈락 패널들에 대한 특성을 파악하여 개인의 인구통계학적 특성 또는 흡연 관련 특성에 의한 것인지를 알 수 있었다. 이 검토 자료는 추후 패널조사 설계 및 수행 시 패널 관리 방법과 효과에 대한 참고자료로 활용될 수 있을 것으로 사료된다.

## Abstract

## A panel study for smokers and its in-depth analysis

Choi Jongyun, Na Kyoungin

Division of Health Hazard Response, Director General for Health Hazard Response, Korea Disease Control and Prevention Agency (KDCA)

Hwang seung-sik

Graduate School of Public Health, Seoul National University

Smoking adversely affects overall health, and is one of the leading causes of adult cancers, such as lung, esophageal, and oral cancer, and of cataracts and diseases such as cardiovascular, respiratory, and infectious diseases. Accordingly, to understand the smoking behavior of adult smokers in Korea and to identify the determinants that affect smoking cessation and re-smoking, an 'Adult Smokers Panel Survey' was conducted from 2015 to 2020 using the 'National Health and Nutrition Survey' of 1,018 adults in Korea. In addition, the characteristics of each factor, such as the change in smoking amount, smoking urge and the frequency of exposure to smoking cessation advertisements of participants, were analyzed during the follow-up surveys conducted over three years (2018-2020) and conducted for two years during the COVID-19 pandemic (2019, 2020). Through these in-depth surveys, the need to prepare a plan to relieve the stress of smokers to improve the induction of smoking cessation and to support a cessation plan for smokers who have not quit smoking was recommended. In particular, the percentage of 'No Attempt to Quit Smoking' increased from 39.4% to 44.3% during two years of the COVID-19 pandemic (2018-2020). In the future, the need for additional research with a panel of a sufficient number of female smokers and the application of customized medical research through the analysis of individual smoking factors based on biological samples of smokers was presented.

# 2020년 노인 결핵검진사업 결과 분석

질병관리청 감염병정책국 결핵정책과 김희애, 신지연, 인혜경, 심은혜\*  
대한결핵협회 조원중, 김윤수

\*교신저자 : ehshim001@korea.kr, 043-719-7310

## 초 록

질병관리청은 결핵 발생과 사망이 높은 만 65세 이상 노인의 결핵을 조기 발견하고, 타인으로서의 전파를 차단하기 위하여 2020년 전국 노인 결핵검진사업을 실시하였다. 검진방법은 이동검진, 방문검진, 검진기관 연계 상시검진으로 이루어졌고, 설문조사와 흉부X선 검사를 1차적으로 실시하여 유증상자·유소견자에 대해 객담검사를 실시하였다. 검진 목표 190,000명 중 134,478명(70.8%)이 검진사업에 참여하였다.

흉부X선 검사(134,467건)와 객담검사(17,647건)를 실시하여 결핵환자 98명(10만 명당 72.9명)을 발견하였고, 이 중, 7명이 약제내성 결핵환자였다. 이는 2020년 결핵신환자 발생률(10만 명당 38.8명)에 비해 약 1.9배 높은 수준으로 남성, 고연령, 지역사회 거주, 독거, 흡연, 결핵 증상이 있는 경우, 결핵 가족력이 있는 경우에 결핵 발생률이 높은 것으로 확인되었다. 또한, 결핵으로 확진된 98명 중 52.0%(51명)가 흉부X선 검사에서 비활동성 결핵으로 확인되었다. 2018~2019년 노인 결핵검진 시범사업을 통해 발견된 결핵환자는 일반 인구집단에 비해 결핵 치료성공률은 높고 사망률은 감소한 것으로 확인되었다. 이는 검진사업을 통해 결핵환자를 조기 발견하고 사후관리 함으로써 치료 순응도가 향상된 결과로 해석된다.

질병관리청은 2021년 전국 노인 결핵검진사업 대상을 취약노인 뿐만 아니라 거동불편 장애인까지 확대하여 추진 중에 있다. 이를 통해 사각지대의 결핵환자를 조기 발견·치료하고 타인으로서의 전파를 차단하여 우리나라 결핵발생률을 낮추는데 기여하고자 한다.

**주요 검색어:** 결핵, 노인, 결핵검진, 흉부X선 검사, 객담검사, 발생률

## 들어가는 말

결핵은 전 세계적으로 매년 1,000만 명 이상이 진단되고 142만 명 이상이 사망하는 질병부담이 높은 질병이다[1]. 우리나라는 2011년(39,557명, 인구 10만 명당 78.9명) 결핵 신환자수 최고치를 기록한 이후 매년 7.3%씩 감소하여 2020년 19,933명(인구 10만 명당 38.8명)까지 감소하였다[2]. 그러나 만 65세 이상 노인 인구의 결핵 발생 및 사망 비율은 매년 증가하였고, 2020년 전체 결핵 환자의 49.1%를 차지하였다[3](그림 1).

이에, 질병관리청에서는 노인 결핵 발생 및 사망 감소를 위해서 2018년과 2019년 노인 결핵검진 시범사업을 실시하고, 검진 프로토콜을 마련하였다. 이를 바탕으로 2020년 노인

결핵검진사업을 전국으로 확대 시행하였다.

이 글에서는 「2020년 노인 결핵검진사업」의 결과를 분석하고 노인 대상 결핵예방관리 정책을 제시하고자 한다.

## 몸 말

2020년 4월부터 12월까지 전국 만 65세 이상 노인을 대상으로 검진을 실시, 총 134,478명이 검진에 참여하였다. 검진 접근성을 높이기 위해 검진차량을 통한 이동 검진, 휴대용 X선 장비를 활용한 방문 검진, 검진기관(복합자의원, 대한결핵협회 지부)과 연계한 상시검진을 실시하여 검진 참여율을 높였다.

그림 1. 2011~2020년 연령별 결핵 신환자 수 및 비율

\*자료원: 2020년 결핵환자 신고현황 연보, 질병관리청

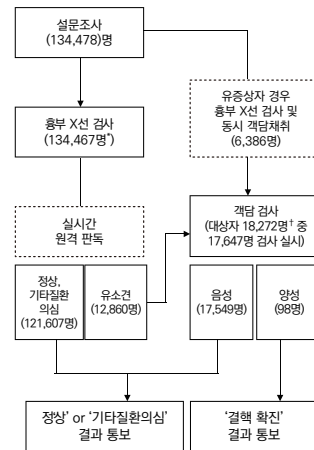

그림 2. 결핵검진 절차

\*흉부X선 검사를 거부한 11명에 대해서는 객담검사만 실시

† 유증상이면서 유소견자인 974명 제외

결핵검진사업 참여에 동의한 대상자들에게 설문조사, 흉부X선 검사 및 실시간 원격판독을 실시하였다. 객담검사는 결핵 유증상자(설문조사 시 2주 이상 기침 응답자) 또는 흉부X선 상 과거 폐결핵을 앓았던 흔적이 있거나 현재 활동성 폐결핵이 의심되는 경우 당일과 익일 객담을 채취하여 검사를 실시하였다. 검사종류는 도말검사, 배양검사, 결핵균핵산증폭검사(이하, PCR), Xpert MTB/RIF(도말 양성자에 한함), 신속감수성검사 및 통상감수성검사(배양 양성자에 한함), 군동정검사(배양 비결핵 항산균에 한함)를 실시하였다(그림 2).

사업 참여자의 일반적 특성, 결핵확진자 및 비활동성 결핵확진자의 임상적 특성은 빈도와 백분율로 나타내었고, 결핵확진자 특성별 결핵 발생 분석을 위해 T검정과 카이제곱 검정을 실시하였다.

## 1. 검진자 및 결핵환자의 일반적 특성

2020년 노인 결핵검진사업의 최우선순위 대상자는 건강보험 가입자보다 결핵발생률이 높은 의료급여수급노인, 검진 접근성이 떨어지는 재가와상노인(장기요양급여 3·4·5등급 판정자 중 자택거주자)이며, 차순위 검진대상자는 독거노인, 차상위계층노인,

허약노인 등이다[2].

검진사업 참여자 134,478명의 일반적 특성은 여성 75.6%(101,626명), 75세 이상 73.4%(98,763명), 의료급여수급자 17.7%(23,849명), 지역사회거주 51.4%(69,127명), 독거 21.8%(29,360명), 기저질환이 있는 경우 41.2%(55,433명), 거동불편자(와상 포함) 50.0%(67,288명), 결핵증상이 있는 경우

### 3. 검진자 및 결핵환자의 검사결과

사업에 참여한 134,478명 중 134,467명이 흉부X선 검사를 실시하였고, 흉부X선 검사를 거부한 11명에 대해서는 객담검사만 실시하였다.

흉부X선 판독결과는 요치료(활동성 폐결핵이거나 결핵성으로 추정), 요관찰(활동성 미정 폐결핵, 결핵의심), 비활동성(과거에 폐결핵이 발생하였으나 현재 치유되어 섬유성 병변 등 흔적이 남아있는 상태), 정상, 기타 질환 의심으로 나뉜다. 검진

참여자의 흉부X선 판독결과는 정상 64.5%(86,742명), 기타 질환 의심 25.9%(34,870명), 비활동성 결핵 8.0%(10,710명), 요관찰 1.5%(1,972명), 요치료 0.1%(173명)로 확인되었다. 설문을 통해 결핵증상이 있거나 흉부X선 상 폐결핵을 앓았던 흔적이 있고 현재 활동성 폐결핵이 의심되는 18,272명 중 객담을 수거한 17,647명을 대상으로 객담검사를 실시하였다. 객담 도말검사 양성률은 0.8%(133명), 객담 배양검사 양성률 0.5%(91명), PCR 양성률 0.2%(33명)였다.

결핵확진자(98명)의 흉부X선 판독결과는 비활동성

## 맺는 말

2020년 노인 결핵검진사업을 통해 만 65세 이상 노인 134,478명에 대해 흉부X선 촬영 등을 통한 결핵검진을 실시하여 결핵환자 98명(10만 명당 72.9명)을 발견하였다. 이는 2020년 결핵신환자 발생률(10만 명당 38.8명)에 비해 약 1.9배 높은 수준이었다[3].

검진사업 우선순위별 환자 발생은 최우선순위 검진대상자(의료 급여수급노인, 재가와상노인)가 차순위 검진대상자(독거노인, 차상위 계층, 허약노인 등)에 비해 결핵 발생이 높았다. 검진 우선순위와 무관하게 독거, 재가와상, 차상위계층, 의료급여수급권자, 허약노인 순으로 발생이 높아짐을 확인할 수 있었다. 이는 기존 선행연구들과 일치하는 결과로 사회·경제적 요인, 건강상태 등이 결핵 발생에 영향을 미친다는 것을 확인할 수 있었다[4].

노인 폐결핵은 임상적, 방사선학적으로 비정형적인 소견을

보이는 경우가 많아 결핵 진단 및 치료의 지연이 발생하고 있어, 결핵 전파의 위험을 높일 수 있는 특성을 지녔다[5,6]. 따라서 노인 폐결핵의 빠른 진단을 위해서는 비정형적 증상 및 흉부X선 소견상 이상을 보일 경우 결핵을 의심하고 객담검사를 실시하여야 한다[7,8]. 본 사업에서는 흉부X선 상 비활동성 결핵 소견자에게도 객담검사를 적극적으로 실시하여 환자 발견율을 높이하고자 하였다. 그 결과 결핵으로 확진된 98명 중 52.0%(51명)가 흉부X선 검사에서 비활동성 결핵이었고, 2주 이상 기침 등 결핵 증상이 없는 환자가 69.4%(68명)에 달해, 노인 결핵은 임상적으로 비정형적인 소견을 보인다는 기존 선행연구 결과와 일치하였다[9]. 따라서 만 65세 이상 노인의 경우 결핵 증상이 없더라도 매년 1회 정기적으로 결핵검진을 실시하는 것이 필요하다.

노인 결핵은 비정형적 특성으로 인해 진단이 늦어지고, 신체 기능 저하 등으로 인하여 약제 부작용 발생 빈도가 높아 치료성공률이 낮은 것으로 보인다. 따라서, 노인 결핵환자를 조기 발견·치료하여 치료 성공률을 높이고 사망률을 감소시키는 것이 중요하다[10]. 2018년, 2019년 노인 결핵검진 시범사업을 통해 발견된 결핵환자의 치료성공률(2018년 82.4%, 2019년 88.7%)은 일반인구집단의 치료성공률(2018년 76.2%, 2019년 74.7%)에 비해서 높았고, 사망률(2018년 12.2%, 2019년 11.3%)은 일반인구집단(2018년 22.3%, 2019년 22.3%)에 비해 감소한 것을 확인할 수 있었다[11,12]. 이는 검진사업을 통하여 환자를 조기 발견하고 치료 연계 등의 사후관리를 통해 치료순응도가 향상되어, 치료성공률은 높아지고 사망률은 감소한 것으로 보인다.

질병관리청은 2021년에도 전국 노인 결핵검진사업을 지속 추진 중에 있다. 검진대상은 결핵검진 기회가 적고 결핵 발생률이 높은 의료급여수급·재가와상·독거 등 사회·경제적으로 취약한 노인들이다[13]. 또한, 신체적·정신적 장애로 인하여 거동이 불편한 장애인들을 대상으로도 찾아가는 결핵 검진을 확대하여 결핵검진 사각지대 해소를 목표로 한다. 이를 통해 결핵환자를 조기 발견하고 치료성공률은 높여 타인으로의 전파를 차단하여 우리나라 결핵발생률을 낮추는데 기여하고자 한다.

### ① 이전에 알려진 내용은?

국내 결핵 환자 수는 지속적으로 감소하고 있으나, 노인의 경우 고령화, 비정형적인 결핵 증상과 면역력 저하, 기저질환, 신체 기능 저하 등으로 결핵 발병 가능성이 높으나 결핵진단이 지연되고 있어 노인층의 결핵 발생률과 사망률이 높아지고 있다.

### ② 새로이 알게 된 내용은?

2020년 노인 결핵검진사업을 통해 134,478명을 검진하여 결핵환자 98명(10만 명당 72.9명)을 발견하였다. 이는 2020년 결핵신환자 발생률(10만 명당 38.8명)의 약 1.9배 높은 수준이다. 검진사업 우선순위별 환자 발생은 최우선순위 검진대상자(의료수급노인 및 재가와상노인)가 결핵 발생이 높아지는 것을 확인하였다. 결핵확진자의 52.0%(51명)는 흉부X선 검사에서 비활동성 결핵이었으나 객담검사를 통해서 결핵으로 확인되었다.

2018~2019년 시범사업을 통해 발견된 결핵환자는 일반 인구집단에 비해 치료성공률이 높고 사망률이 감소한 것으로 확인되었다.

### ③ 시사점은?

노인결핵 발생률·사망률 감소를 위해서는 결핵검진 기회가 적고 결핵 발생률이 높은 취약노인에게 찾아가는 결핵검진을 실시하고 흉부X선 상 비활동성 결핵이더라도 객담검사를 실시하여 적극적으로 환자를 발견해낼 필요가 있다. 또한, 의료복지시설 거주자에 비하여 지역사회 거주자에게서 결핵발생이 높은 것으로 확인되었다. 노인의료복지시설 거주자에 대한 의무검진 제도로 인해 결핵환자를 조기 발견하게 되어 결핵발생률이 낮게 나타났을 가능성이 있다.

**Abstract**

## Results of the 2020 elderly Tuberculosis (TB) screening in Republic of Korea

Kim HeeAe, Shin JeeYeon, In HyeKyung, Shim Eunhye

Division of Tuberculosis Prevention and Control, Korea Disease Control and Prevention Agency (KDCA)

Joe WeonJung, Kim YunSoo

Korean National Tuberculosis Association

The Korea Disease Control and Prevention Agency (KDCA) conducted an early-stage tuberculosis (TB) screening project for the elderly in 2020. The aim was to detect TB in seniors over the age of 65 living in regions with high TB incidences and high TB-related deaths, and to prevent transmission.

The screening method consisted of mobile examinations, visiting examinations, and regular examinations linked to examination institutions, and the examination survey and chest X-ray examination were conducted primarily, and a sputum examination was conducted for abnormal findings of chest X-ray and TB symptoms.

134,478 people were participated in total. Chest x-ray (134,467) and sputum tests (17,647) were performed and 98 TB patients (72.9 per 100,000 population) were reported.

This was about 1.9 times higher than the incidence of TB in the general population (38.8 people per 100,000 population, 19,933 people). In the case of males, the elderly people, smokers, community residences, living alone, symptoms of TB, and histories of TB within the family show increased the TB incidence. In addition, 52.0% (51) of TB confirmed patients were identified as having inactive TB chest X-ray examination.

Furthermore, as a result of analyzing the treatment success rate of TB patients in a 2018-2019 project for TB screening for the elderly, it was found that the treatment success rate was higher than that of the general population. This confirmed that early detection and follow-up of TB patients increased the success rate of treatment for TB.

The KDCA continued its elderly TB screening project in 2021. Through this, early detection and treatment of TB patients will prevent transmission. It intends to contribute to lowering the incidence of tuberculosis in Korea.

## 만성질환 통계

## 1. 현재흡연율 추이, 2007~2019

◆ 만 19세 이상 현재흡연율(연령표준화)은 2007년 25.3%에서 2019년 21.5%로 지난 12년 동안 3.8%p 감소되었음(남자는 45.1%에서 35.7%로 9.4%p 감소되었고, 여자는 5.3%에서 6.7%로 1.4%p 증가되었음). 2019년 기준 남자의 흡연율이 여자에 비해 5.3배 높았음(그림 1).

그림 1. 현재흡연율 추이, 2007~2019

\* 현재흡연율 : 평생 담배 5갑(100개비) 이상 피웠고 현재 담배를 피우는 분율, 만 19세 이상

※ 연도별 지표값은 2005년 추계인구로 연령표준화

## 2. 현재흡연자의 금연시도 및 금연계획률 추이, 2007~2019

◆ 만 19세 이상 현재흡연자의 금연시도율(연령표준화)은 2007년 60.7%에서 2019년 53.8%로 6.9%p 감소하였으며, 1개월 내 금연계획률(연령표준화)은 2007년 20.2%에서 2019년 17.2%로 3.0%p 감소하였음. 2019년 기준 현재흡연자 10명 중 5.4명이 금연을 시도하였고, 1.7명이 향후 1개월 내 금연계획이 있다고 응답하였음(그림 2).

그림 2. 현재흡연자의 금연시도 및 금연계획률 추이, 2007~2019

\* 현재흡연자의 금연시도율 : 현재흡연자 중 최근 1년 동안 담배를 끊고자 하루(24시간) 이상 금연을 시도한 분율

† 현재흡연자의 1개월 내 금연계획률 : 현재흡연자 중 1개월 내 금연할 계획이 있는 분율

※ 연도별 지표값은 2005년 추계인구로 연령표준화

## Noncommunicable Disease (NCD) Statistics

# 1. Trend of current smoking rates among Korean adults aged 19 and over, 2007–2019

◆ For the past 12 years (2007–2019), the overall current smoking rate among Korean adults aged 19 and over fell by a decrease of 3.8 percentage points (%p), from 25.3% in 2007 to 21.5% in 2019: 45.1% to 35.7% among men (9.4%p decrease) and 5.3% to 6.7% among women (1.4%p increase). In 2019, the current smoking rate of men stood at 35.7%, 5.3 times higher than 6.7% of women (Figure 1).

Figure 1. Current smoking rates among Korean adults (aged  $\geq 19$  years), 2007–2019

\* Current smoking rate: percentage of people who have smoked more than 5 packets (100 cigarettes) in their lifetime and are currently smoking, among those aged 19 years and over

※ The mean was calculated using the direct standardization method based on a 2005 population projection.

## 2. Percentage of those who have attempted to stop smoking and have stop-smoking plan among current smokers aged $\geq 19$ years, South Korea, 2007–2019

◆ The percentage of those who have attempted to stop smoking among current smokers aged 19 and over declined from 60.7% in 2007 to 53.8% in 2019 (a decrease of 6.9% percentage point [%p]). Meanwhile, the percentage of those planning to stop smoking within one month dropped from 20.2% in 2007 to 17.2% in 2019 (a decrease of 3.0%p). The 2019 data indicated that 5.4 out of 10 current smokers had attempted to stop smoking, and 1.7 responded that they had plan to stop within the next one month (Figure 2).

**Figure 2.** Percentage of those who have attempted to stop smoking and have stop-smoking plan among current smokers, 2007–2019

\* Current smoker's rate of attempt to stop smoking: The percentage of current smokers who have attempted to stop smoking more than 24 hours per day in the past year

† Current smoker's stop-smoking plan rates within one month: The percentage of current smokers planning to stop smoking within one month

※ The mean was calculated using the direct standardization method based on a 2005 population projection.

## 1.2 환자감시 : 표본감시 감염병 주간 발생 현황 (21주차)

### 1. 인플루엔자 주간 발생 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주 인플루엔자 표본감시(전국 200개 표본감시기관) 결과, 의사환자분율은 외래환자 1,000명당 1.7명으로 지난주(2.3명) 대비 감소

※ 2020-2021절기 유행기준은 5.8명/(1,000)

그림 1. 외래 환자 1,000명당 인플루엔자 의사환자 발생 현황

### 2. 수족구 발생 주간 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주차 수족구병 표본감시(전국 97개 의료기관) 결과, 의사환자 분율은 외래환자 1,000명당 0.8명으로 전주 0.2명 대비 증가

※ 수족구병은 2009년 6월 법정감염병으로 지정되어 표본감시체계로 운영

그림 2. 외래 환자 1,000명당 수족구 발생 현황

▶ 자세히 보기 : 질병관리청 → 간행물·통계 → 감염병발생정보 → 표본감시주간소식지

### 3. 안과 감염병 주간 발생 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주차 유행성각결막염 표본감시(전국 90개 의료기관) 결과, 외래환자 1,000명당 분율은 5.2명으로 전주 4.9명 대비 증가
- 동기간 급성출혈성결막염의 환자 분율은 0.5명으로 전주 0.4명 대비 증가

그림 3. 외래 환자 1,000명당 유행성각결막염 발생 현황

그림 4. 외래 환자 1,000명당 급성출혈성결막염 발생 현황

#### 4. 성매개감염병 주간 발생 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주 성매개감염병 표본감시기관(전국 보건소 및 의료기관 588개 참여)에서 신고기관 당 사람유두종바이러스 감염증 4.1건, 성기단순포진 2.5건, 침규콘딜롬 2.2건, 1기 매독 1.5건, 클라미디아감염증 1.4건, 임질 1.3건, 2기 매독 0.0건, 선천성 매독 0.0건을 신고함.

\* 제21주차 신고의료기관 수: 임질 12개, 클라미디아감염증 31개, 성기단순포진 35개, 침규콘딜롬 19개, 사람유두종바이러스 감염증 28개, 1기 매독 2개, 2기 매독 0개, 선천성 매독 0개

\*\* 2020.1.1.일부터 사람유두종바이러스 감염증이 표본감시에 신설되었으며, 매독이 전수감시에서 표본감시로 변경됨

### 1.3 수인성 및 식품매개 감염병 집단발생 주간 현황 (21주차)

#### ▣ 수인성 및 식품매개 감염병 집단발생 주간 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주에 집단발생이 14건(사례수 192명)이 발생하였으며 누적발생건수는 213건(사례수 3,032명)이 발생함.

그림 5. 수인성 및 식품매개 감염병 집단발생 현황

## 2.1 병원체감시 : 인플루엔자 및 호흡기바이러스 주간 감시 현황(21주차)

### 1. 인플루엔자 바이러스 주간 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주에 전국 52개 감시사업 참여의료기관에서 의뢰된 호흡기검체 74건 중 양성 없음.

그림 6. 인플루엔자 바이러스 검출 현황

### 2. 호흡기 바이러스 주간 현황(21주차, 2021. 5. 22. 기준)

- 2021년도 제21주 호흡기 검체에 대한 유전자 검사결과 86.5%의 호흡기 바이러스가 검출되었음.  
(최근 4주 평균 87개의 호흡기 검체에 대한 유전자 검사결과를 나타내고 있음)

※ 주별통계는 잠정통계이므로 변동가능

## 2.2 병원체감시 : 급성설사질환 바이러스 및 세균 주간 감시 현황 (20주차)

### ▣ 급성설사질환 바이러스 및 세균 주간 검출 현황(20주차, 2021. 5. 15. 기준)

- 2021년도 제20주 실험실 표본감시(17개 시·도 보건환경연구원 및 70개 의료기관) 급성설사질환 원인 바이러스 검출 건수는 23건(47.9%), 세균 검출 건수는 11건(8.2%) 이었음.

#### ◆ 급성설사질환 바이러스

주			검체수	검출 건수(검출률, %)				
				노로바이러스	그룹 A 로타바이러스	장내 아데노바이러스	아스트로바이러스	사포바이러스
2021	17	75	17(22.7)	0(0.0)	1(1.3)	6(8.0)	0(0.0)	24(32.0)

## 2.3 병원체감시 : 엔테로바이러스 주간 감시 현황 (20주차)

### ▣ 엔테로바이러스 주간 검출 현황(20주차, 2021. 5. 15. 기준)

- 2021년도 제20주 실험실 표본감시(17개 시·도 보건환경연구원, 전국 60개 참여병원) 결과, 엔테로바이러스 검출률 0.0%(0건 양성/1검체), 2021년 누적 양성률 1.1%(2건 양성/181검체)임.
- 무균성수막염 0건(2021년 누적 1건), 수족구병 및 포진성구협염 0건(2021년 누적 0건), 합병증 동반 수족구 0건(2021년 누적 0건), 기타 0건(2021년 누적 0건)임.

#### ◆ 무균성수막염

그림 7. 무균성수막염 바이러스 검출수

### 3.1 매개체감시 / 말라리아 매개모기 주간 감시현황 (20주차)

#### ▣ 말라리아 매개모기 주간 검출 현황(20주차, 2021. 5. 15. 기준)

- 2021년도 제20주 말라리아 매개모기 주간 발생현황(3개 시·도, 총 50개 채집지점)
  - 전체모기 : 평균 4개체로 평년 10개체 대비 6개체 감소 및 전년 9개체 대비 5개체 감소
  - 말라리아 매개모기 : 평균 1개체로 평년 0개체 대비 1개체 증가 및 전년 0개체 대비 1개체 증가
- ※ 모기수 산출법 : 1주일간 유문등에 채집된 모기의 평균수(개체수/트랩/일)
- ※ 2020년에는 보건소·보건환경연구원의 현안업무(코로나바이러스감염증-19) 대응으로 14주차 미채집

그림 10. 말라리아 매개모기 검출수

### 3.2 매개체감시 / 일본뇌염 매개모기 주간 발생 현황 (21주차)

#### ▣ 일본뇌염 매개모기 주간 발생 현황 (21주차, 2021. 5. 22. 기준)

- 2021년 제21주 일본뇌염 매개모기 주간 발생현황 : 9개 시·도 보건환경연구원(총 9개 지점)
  - 전체모기 수 : 평균 21개체 [평년 132개체 대비 111개체 감소 및 전년 41개체 대비 20개체 감소]
  - 일본뇌염 매개모기 : 평균 1개체 [평년 0개체 대비 1개체 증가 및 전년 0개체 대비 1개체 증가]

그림 11. 일본뇌염 매개모기 주간 발생 현황

## 주요 통계 이해하기

〈통계표 1〉은 지난 5년간 발생한 법정감염병과 2021년 해당 주 발생현황을 비교한 표로, 금주 환자 수(Current week)는 2021년 해당 주의 신고건수를 나타내며, 2021년 누계 환자수(Cum, 2021)는 2021년 1주부터 해당 주까지의 누계 건수, 그리고 5년 주 평균 환자수(5-year weekly average)는 지난 5년(2016~2020년) 해당 주의 신고건수와 이전 2주, 이후 2주의 신고건수(총 25주) 평균으로 계산된다. 그러므로 금주 환자수(Current week)와 5년 주 평균 환자수(5-year weekly average)의 신고건수를 비교하면 해당 주 단위 시점과 예년의 신고 수준을 비교해 볼 수 있다. 연도별 환자수(Total no. of cases by year)는 지난 5년간 해당 감염병 현황을 나타내는 확정 통계이며 연도별 현황을 비교해 볼 수 있다.

예) 2021년 12주의 5년 주 평균 환자수(5-year weekly average)는 2016년부터 2020년의 11주부터 14주까지의 신고 건수를 총 25주로 나눈 값으로 구해진다.

$$* \text{5년 주 평균 환자수(5-year weekly average)} = (X1 + X2 + \dots + X25) / 25$$

	11주	11주	12주	13주	14주
			해당 주		
2021년					
2020년	X1	X2	X3	X4	X5
2019년	X6	X7	X8	X9	X10
2018년	X11	X12	X13	X14	X15
2017년	X16	X17	X18	X19	X20
2016년	X21	X22	X23	X24	X25

〈통계표 2〉는 17개 시·도 별로 구분한 법정감염병 보고 현황을 보여 주고 있으며, 각 감염병별로 최근 5년 누계 평균 환자수(Cum, 5-year average)와 2021년 누계 환자수(Cum, 2021)를 비교해 보면 최근까지의 누적 신고건수에 대한 이전 5년 동안 해당 주까지의 평균 신고건수와 비교가 가능하다. 최근 5년 누계 평균 환자수(Cum, 5-year average)는 지난 5년(2016~2020년) 동안의 동기간 신고 누계 평균으로 계산된다.

기타 표본감시 감염병에 대한 신고현황 그림과 통계는 최근 발생양상을 신속하게 파악하는데 도움이 된다.

## Statistics of selected infectious diseases

Cum: Cumulative counts from 1st week to current week in a year

\* The reported data for year 2020, 2021 are provisional but the data from 2016 to 2019 are finalized data.

<sup>†</sup> According to surveillance data, the reported cases may include all of the cases such as confirmed, suspected, and asymptomatic carrier in the group.<sup>§</sup> Cum, 5-year average is mean value calculated by cumulative counts from 1st week to current week for 5 preceding years.

## About PHWR Disease Surveillance Statistics

The Public Health Weekly Report (PHWR) Disease Surveillance Statistics is prepared by the Korea Disease Control and Prevention Agency (KDCA). These provisional surveillance data on the reported occurrence of national notifiable diseases and conditions are compiled through population-based or sentinel-based surveillance systems and published weekly, except for data on infrequent or recently-designated diseases. These surveillance statistics are informative for analyzing infectious disease or condition numbers and trends. However, the completeness of data might be influenced by some factors such as a date of symptom or disease onset, diagnosis, laboratory result, reporting of a case to a jurisdiction, or notification to Korea Disease Control and Prevention Agency. The official and final disease statistics are published in infectious disease surveillance yearbook annually.

## Using and Interpreting These Data in Tables

- **Current Week** – The number of cases under current week denotes cases who have been reported to KDCA at the central level via corresponding jurisdictions(health centers, and health departments) during that week and accepted/approved by surveillance staff.
- **Cum. 2021** – For the current year, it denotes the cumulative(Cum) year-to-date provisional counts for the specified condition.
- **5-year weekly average** – The 5-year weekly average is calculated by summing, for the 5 preceding years, the provisional incidence counts for the current week, the two weeks preceding the current week, and the two weeks following the current week. The total sum of cases is then divided by 25 weeks. It gives help to discern the statistical aberration of the specified disease incidence by comparing difference between counts under current week and 5-year weekly average.

For example,

\* 5-year weekly average for current week=  $(X1 + X2 + \dots + X25) / 25$

	10	11	12	13	14
2021			Current week		
2020	X1	X2	X3	X4	X5
2019	X6	X7	X8	X9	X10
2018	X11	X12	X13	X14	X15
2017	X16	X17	X18	X19	X20
2016	X21	X22	X23	X24	X25

- **Cum. 5-year average** – Mean value calculated by cumulative counts from 1<sup>st</sup> week to current week for 5 preceding years. It gives help to understand the increasing or decreasing pattern of the specific disease incidence by comparing difference between cum. 2021 and cum. 5-year average.
